## CENTRE OF PLANNING AND ECONOMIC RESEARCH

The Centre of Planning and Economic Research (KEPE) was established as a research unit, under the title "Centre of Economic Research", in 1959. Its primary aims were the scientific study of the problems of the Greek economy, encouragement of economic research and cooperation with other scientific institutions.

In 1964, the Centre acquired its present name and organizational structure, with the following additional objectives: (a) The preparation of short, medium and long-term development plans, including plans for regional and territorial development and also public investment plans, in accordance with guidelines laid down by the Government. (b) The analysis of current developments in the Greek economy along with appropriate short-term and medium-term forecasts; also, the formulation of proposals for appropriate stabilization and development measures. (c) The further education of young economists, particularly in the fields of planning and economic development.

The Centre has been and is very active in all of the above fields, and carries out systematic basic research in the problems of the Greek economy, formulates draft development plans, analyses and forecasts short-term and medium-term developments, grants scholarships for post-graduate studies in economics and planning and organizes lectures and seminars.

Within the framework of these activities, the Centre also publishes studies from research carried out at the Centre, reports which are usually the result of collective work by groups of experts which are set up for the preparation of development programmes, and lectures given by specially invited distinguished scientists.

The Centre is in continuous contact with similar scientific institutions abroad and exchanges publications, views and information on current economic topics and methods of economic research, thus further contributing to the advancement of the science of economics in the country.

## DISCUSSION PAPER SERIES

This series of Discussion Papers is designed to speed up the dissemination of research work prepared by the staff of KEPE and by its external collaborators with a view to subsequent publication. Timely comment and criticism for its improvement is appreciated.

## ACKNOWLEDGEMENTS

We wish to thank our KEPE colleagues, especially Elias Migas and Stella Balfoussias, for their valuable comments on our work which was presented in a KEPE workshop on the 24th September 1993. We are also deeply indebted to Zvi Griliches, Ernst R. Berndt and the productivity group at the NBER, from whom we have greatly benefitted in seminar and private discussions.

### ABSTRACT

Despite their importance as economic performance indicators, productivity indices are not officially available in Greece for any economic sector. This paper uses the growth accounting framework to estimate partial and total factor productivity indices for the manufacturing sector during 1980-1991. The capacity utilization is estimated by assuming capital to be a quasi-fixed factor. The resulting data base appears for the first time in Greece. It is particularly useful for scientifically founded economic policy analysis. Among the most apparent policy suggestions of this data set may be the promotion of industries characterized as "dynamic", like the "Fats and Oils", and "Office Equipment".

### 1. Introduction

Recently, a lot of discussion is taking place not only in Greece, but also among its European partners, about the disappointing performance of the Greek economy and its possible relationship to productivity growth. Unfortunately, despite their importance as measures of economic performance, productivity indices are not officially available in Greece.<sup>1</sup> However, a falling rate of growth of productivity may imply a falling rate of growth of real per capita income with a resulting drop in the standard of living of the Greek population. It is also possible that phenomena, like the observed high and persistent inflation, as well as the chronic imbalances in the international payments of the country, are closely related to falling rates of productivity growth.

Productivity is broadly defined as the real output per unit of input, and it is expressed in the form of indices which measure the relative efficiency<sup>2</sup> that an economy or sector operates at a macro or micro level.

Productivity increase is one of the most important sources of growth of total output and income. Denison (1974) estimated that during 1929-1969 the 47% of the increase in the real national income of the U.S.A. was due to the increase of output per unit of input, and only the rest, 53%, was due to increases of real inputs. Moreover, regarding the increase of real national income per employee, Denison estimated that during the same period the share of output per unit of input was 79% and the rest was due to increases in the inputs of education and physical capital.<sup>3</sup>

In general, an increase in real income that comes from an increase in productivity implies an equivalent increase in the real compensation of the factors of production, whose real income can only change through an income redistribution. To make this explicit, let us assume that we have only one input, say labor, L. The ratio Q/L, where Q is real output, is

<sup>&</sup>lt;sup>1</sup>. The only available productivity estimates are published by IOBE (Research Institute of Greek Industries) on a quarterly basis at the 2-digit level of the International Standard Industrial Classification. The IOBE figures include only a labor productivity index which is defined as the ratio of the index of industrial production for manufacturing, compiled by the National Statistical Service of Greece, to an unweighted employment index.

<sup>&</sup>lt;sup>2</sup>. Within the context of production functions, in general, a production unit is efficient if it maximizes its output with a given set of inputs, or, if it minimizes its inputs producing a given output, taking into account cost considerations as well.

<sup>&</sup>lt;sup>3</sup>. Other authors give somewhat different estimates of the contribution of productivity change to the growth of output. See the classic debate between Denison (1969) on the one hand, and Jorgenson and Griliches (1967, 1972) on the other. Also, see Christensen et al. (1980).

an index of labor productivity. This ratio implies that if productivity is constant, then output can increase only if we use more units of labor. All additional output will compensate the additional units of labor at the prevailing prices, and there will be no surplus left to raise the level of real factor compensation for the providers of either the original or the added units. By generalizing for more than one inputs, the above example implies that the providers of any one input could increase their real compensation only at the expense of the providers of some other input, or, in other words, by a redistribution of income. In contrast, if productivity is rising, then all factors' real income can increase without a necessary decrease in the real income of some other factors.

Thus, we can observe that prices may remain constant if we choose to increase real incomes through an increase in productivity. The reason is that the unit factor cost remains unchanged. For instance, if output increases by 5% while labor remains constant, and if the compensation of labor per work hour, w, increases also by 5%, then the unit labor cost, wL/Q, will remain constant. Also, a proportional increase in both, the hour compensation of labor and productivity, will not change the share of labor. In other words, keeping L constant, a 5% increase in both, Q and w, will result to the ratio 1.05wL/1.05Qp, where p is the price of output. These results remain the same independently of whether the increase in productivity takes place through a reduction in the work hours with output constant, or through a combination of an increase in output and a reduction in labor hours.

Consequently, the compensation of the factors' of production per unit of input, measured in current prices, can increase by the same rate as the productivity increase, without a necessary increase in the average price of output. In general, the nominal compensation of the factors' of production can increase faster than the increase in prices, or slower than the decrease in prices. The difference is proportional to the rate of change of productivity.

Summing-up, an increase in the compensation of labor proportional to the increasing trend of average productivity of labor has two interesting properties: (1) The increase in the labor compensation is not inflationary. (2) The increase in the compensation of labor does not necessarily change the distribution of output between labor and the other inputs.

Based on the above argument, governments may use the concept of average productivity as a guide for their incomes policy.<sup>1</sup> However, such an incomes policy presupposes that the share of labor in output remains constant. If it does not, then an incomes policy based on the average productivity would freeze the relative shares of the factors of production which normally change because of the changing economic conditions. Moreover, regarding this issue, interpretation of productivity indexes is crucial. Changes in

<sup>&</sup>lt;sup>1</sup>. The first major use of these properties of average labor-productivity change took place in the U.S.A. in the 1948 and 1950 collective bargaining agreements between the General Motors Corporation and the United Automobile Workers.

labor productivity may be considered as changes in the effort that workers are putting. However, such a measure of partial productivity is influenced by other factors as well, like changes in technology, in the capital/labor ratio, in the inputs of intermediate goods, in the rates of capacity utilization, and also by the interrelationships of these factors.

The necessity to have productivity officially measured is also dictated by the following two needs: (1) To measure and predict the potential GNP and the labor requirements. (2) To analyze the business cycle and design the proper monetary and fiscal policies.

The potential GNP is estimated on the basis of labor force growth, the average work hours per week, and the output per work hour in combination with some assumption about unemployment at a high level of employment. Regarding the analysis of business cycles, it is well known that the output per work hour decreases or increases at a lower rate when there is a downturn of economic activity. It has been observed that the output is reduced more than work hours during depression, because the production of any quantity of output requires a relatively bigger number of employees, especially during the first stages of a depression. In addition, some workers may be kept even without full time employment for various business reasons. During booms opposite effects are observed.

Taking into account the dissatisfactory situation of the Greek economy, as well as the pressing need for a scientifically based economic policy in Greece, it would be very useful to create a productivity data base, starting from the agricultural<sup>1</sup> and manufacturing sectors where the data availability is satisfactory. The purpose of this paper, which is based on our KEPE study on productivity measurement, is to present our estimates of total factor and partial productivity growth at the three-digit International Standard Industrial Classification level of the manufacturing sector of Greece for the time period 1980-1991. Our estimates constitute a data base, which appears for the first time in Greece, and which will be very useful for statistical, econometric, and policy analysis, not only within the national boundaries of Greece, but also within the European Union, of which Greece is a member. The methodological framework of our work is the growth accounting approach to productivity measurement, based on the translog production functions. The following section gives a brief but comprehensive presentation of the economic theory of productivity. The third section describes the empirical foundation of our work, while the fourth section presents and discusses the estimated total factor and partial productivity indices. Finally, the last section summarizes the results and concludes the paper.

<sup>&</sup>lt;sup>1</sup>. Zoe Georganta (1993) has estimated total factor and partial productivity indices for the agricultural sector of Greece for the time period 1974-1989.

#### 2. The Economic Theory of Productivity

The conceptual framework for the measurement of productivity is found in the theory of production and cost. There are two approaches to productivity measurement<sup>1</sup>: Growth accounting and econometric fitting of production functions. Both approaches have recently been summarized by Diewert (1980, 1989) and Morrison and Diewert (1990). Diewert (1976) derived the formal relationship between growth accounting and econometric fitting of production functions and econometric fitting of production functions and he showed that both approaches equivalent. He proved that under cost minimizing behavior, and by utilizing a translog mathematical formulation, the input-quantity or the input-price aggregate can be equivalently calculated by means of either the Tornquist index, or the translog production or cost function.

The growth accounting approach to productivity measurement starts with a production function of the following form:

$$\mathbf{Q} = \mathbf{F}(\mathbf{L}, \mathbf{K}, \mathbf{M}; \mathbf{t}) \tag{1}$$

where the volume of output, Q, is a function of the volume of services of the factors of production: labor (L), capital (K), intermediate inputs (M), and the level of productive efficiency which is a function of time, t.

The following assumptions are made: (1) F is logarithmically differentiable and exhibits constant returns to scale. According to Morrison (1986) the assumption of constant returns to scale is not crucial. However, Hauser and Yee (1992) argue that she is incorrect. (2) Each input is paid the value of its marginal product. (3) Technical change is Hicks neutral.<sup>2</sup> Then, equation (1) can be written as,

$$dlogY/dt = (\partial logY/\partial logL)(dlogL/dt) + (\partial logY/\partial logK)(dlogK/dt) + + (\partial logY/\partial logM)(dlogM/dt) + (\partial logY/\partial t)$$
(2)

If  $d\log Y/dt = Y/Y$ ,  $\partial \log Y/\partial t = P/P$ , then, equation (2) can be expressed as,

<sup>&</sup>lt;sup>1</sup>. Recently, a group of researchers argue that productivity growth is an unbiased estimate only if the estimation procedure takes explicit account of the change in efficiency in the Farrell (1957) sense. See Grosskopf (1993).

<sup>&</sup>lt;sup>2</sup>. Hicks neutral advance requires an unchanged ratio of marginal products when factor proportions are constant. For a recent comprehensive overview of definitions of neutral technical change, see Fare and Chambers (1991).

P/P = Y/Y - an elasticity weighted aggregate input growth

Equation (3) measures Total Factor Productivity (TFP) growth. Thirtle and Bottomley (1992, pp.384-385) have shown that equation (3) is also the result of a production function derivation of a TFP growth index.

(3)

If p denotes the price of inputs, and q denotes the price of output, then, equation (3) can be written as,

$$P/P = p/p - q/q \tag{4}$$

Equation (4) implies the basic accounting identity:

$$\Sigma q Y = \Sigma p X \tag{5}$$

X represents aggregate input. The prices p and q correspond to the deflators used in order to transform values into real prices. Equ.(3) and (4) hold if we use the Divisia indexes, which are defined as:

$$Y/Y = \Sigma w_i Y_i/Y_i \quad X/X = \Sigma v_j X_j/X_j$$
(6)

and

$$q/q = \Sigma w_i q_i/q_i \quad p/p = \Sigma v_j p_j/p_j$$
(7)

The weights  $w_i$ ,  $v_j$  are the relative shares of the ith output in total value of output, and the jth input in total value of input, respectively,

$$\mathbf{w}_{i} = \mathbf{q}_{i} \mathbf{Y}_{i} / \Sigma \mathbf{q}_{i} \mathbf{Y}_{i}, \quad \mathbf{v}_{j} = \mathbf{p}_{j} \mathbf{X}_{j} / \Sigma \mathbf{p}_{j} \mathbf{X}_{j}, \quad \Sigma \mathbf{w} = \Sigma \mathbf{v} = 1$$
(8)

The weights w and v are arithmetic averages of the relative shares in the two periods considered.

Divisia indices are the result of the following process: We differentiate equ.(5) with respect to time and we divide both sides by the corresponding total value. The result is the following equation:

$$Y_1(dq_1/dt) + q_1(dY_1/dt) + ... = X_1(dp_1/dt) + p_1(dX_1/dt) + ...$$
 (9)

By defining the growth rates as,

q = dq/dt, Y = dY/dt, p = dp/dt, X = dX/dt, q/q = dlnq/dt =

$$= \Delta q/q = (q_t - q_{t-1})/q_{t-1}, \qquad (10)$$

we get the following equation:

$$\Sigma w_{i}[q_{i}/q_{i} + Y_{i}/Y_{i}] = \Sigma v_{i}[p_{i}/p_{i} + X_{i}/X_{i}]$$
(11)

Consequently, the growth rate of TFP can be expressed as:

$$P/P = \Sigma w Y/Y - \Sigma v X/X$$
(12)

or

 $P/P = \Sigma w p/p - \Sigma v q/q$ (13)

Thus, Divisia price indices are dual to Divisia quantity indices.

Changes in TFP reflect the net saving in the real cost of production achieved over time, or, in other words, increases in productive efficiency in general. The main force behind increases in TFP (assuming comparable rates in capacity utilization) is cost-reducing technological progress. But other factors affect TFP as well. Among them are economies of scale, changes in the quality of resources, and inter-industry shifts in resources.

Partial productivity indices are obtained on the basis of.

equation (3) as a difference between Y/Y and the growth rate of only one input. Thus, the partial productivity indices are simply the average products of the corresponding factors, while the TFP index is often referred to as the residual, or the index of technical progress. Partial productivity indices show the savings that have been achieved over time in the use of each input per unit of output. Their changes reflect not only changes in productive efficiency, but also changes in factor substitutions that are the result of changes in relative factor prices.

According to the definitions of partial and total factor productivity, changes in partial productivity reflect movements along the production function, as the proportions of inputs change. They also reflect shifts in the production function which are due to technical change. For example, changes in the ratio of output to labor, Q/L, are influenced by changes in the factor substitution, as well as by changes in the productive efficiency, as this is measured by TFP. Thus, if total input is denoted by X, then the following equation holds for labor productivity:

#### $Q/L = Q/X \bullet X/L$

On the other hand, the difference between the rates of growth of labor input and labor-capital inputs combined reflects the rate of substitution of capital for labor. Also, the concept of changes in the ratio of output to labor depends on how we define each term of this ratio. Let us assume that the labor input is measured by non-differentiated hours worked, and the weights for the quantities of products are either factor costs (value added per unit of output), or prices. Then, the change in output per hour, measured for a class of products and industries, reflects relative shifts of production among products with different ratios of costs or prices to hours in the base period, as well as productivity changes in producing each of these products. Similarly, if there are relative shifts of production to less capital intensive industries (and thus more value added relative to capital input), then the aggregate output/capital ratio increases even though the requirements of capital per unit of output remain constant in all individual industries. If production shifts to industries with less energy requirements per unit of output, the effect of this shift increases the corresponding ratio of partial productivity.

The next section discusses problems relating to the empirical measurement of Greek manufacturing output and input indices. Also, it presents the data base used in this paper.

#### 3. Empirical Measurement of Productivity

The two most often used indices of measuring TFP growth are Solow's (1957) geometric index and Kendrick's (1961) arithmetic measure. Solow's TFP change measure is based on the Cobb-Douglas production function, with constant returns to scale, autonomous and neutral technological change, and perfect competition. It is expressed as follows:

$$dP/P = dY/Y - (\sum v_j dX/X), \sum v_j = 1$$
 (15)

where d denotes time derivatives.

Kendrick measures TFP growth by using the Euler condition and a distribution equation derived from a homogeneous production function with constant elasticity of substitution and disembodied neutral technical change. It is written as

$$dP/P = \{(Y_1/Y_0)/[(\sum v_j X_1)/(\sum v_j X_0)]\}^{-1}$$
(16)

where the subscripts 1 and 0 refer to current and base period respectively. Levhari and al. (1966) have shown that the two measures are equivalent for small changes in the quantities of inputs and outputs.

For discrete data, formula (15) can be used to measure TFP and partial productivity indices by employing the Tornqvist-Theil index<sup>1</sup>, which is defined as follows:

$$TFP = P/P = \sum w_{it} [\log Y_{it} - \log Y_{i,t-1}] - \sum v_{jt} [\log X_{jt} - \log X_{j,t-1}]$$
(17)

Formula (17) is the productivity growth index<sup>2</sup> which has been used by many authors

$$Pr_{F} \equiv Q_{F}/Q_{F}^{*}$$
 (18)  
where,  $Q_{F}$  is the output index, and is given by  $Q_{F} \equiv [Q_{L} Q_{P}]^{1/2}$ ,  $Q_{F}^{*}$  is the corresponding input index, and  $Q_{L}$ ,  $Q_{P}$  denote Laspeyres and Paasche indices, respectively.

<sup>1.</sup> The discrete and continuous index numbers are equal if relative shares are constant; otherwise an error is involved which depends on the variability of shares and the length of the time period. Divisia indices for discrete time satisfy the time reversal test, and as Theil (1967) has demonstrated, they also satisfy the factor reversal test.

<sup>2.</sup> In a recent paper, Diewert (1992) proves that the Fisher ideal productivity index,  $Pr_F$ , described by the following formula (18), is superior to formula (17) from both viewpoints, the test approach to index numbers, and the economic approach to productivity indices which assumes optimizing behavior.

like Christensen and Jorgenson (1970), Jorgenson and Griliches (1967, 1972), the U.S. Bureau of Labor Statistics [see Mark and Waldorf (1983, p.15)], and more recently by Thirtle and Bottomley (1992) in agriculture.

Regarding the primary inputs of labor and capital, some methodological issues have traditionally been raised. Estimates, parametric or non-parametric, of factor productivity are sensitive to the methods used for measuring real factor inputs in general and the classification of the quantity and quality of each input into its various elements. Such issues have also been very controversial [see the classic debate between Jorgenson and Griliches (1967, 1972) on the one hand, and Denison (1969) on the other].

Starting with the labor input, the main issues involved in the case of the Greek manufacturing sector are age-sex composition, educational attainment, and training-skill qualifications of the labor force. Due to lack of such data for the Greek manufacturing sector, our labor input is not adjusted for characteristics relating to age-sex composition, as well as educational and skill qualities of the labor force. However, such an adjustment of our labor input, if we had the data to implement it, would involve conceptual problems, like the double character of education as both an investment and a consumption good, the quality of education, and the existence of externalities associated with education. All these issues make the quality adjustment of the labor input very difficult in general.

In relation to the capital input, the problems are too well-known to necessitate a long discussion. Data on manufacturing capital stock for Greece have been estimated by Skountzos and Mattheou (1991). They distinguish four capital stock categories: buildings, other construction works, machinery, and transport equipment. This capital stock data base has been obtained by the perpetual inventory method. It extends as back as 1950 for all sectors of the Greek economy. It is officially used by the Greek government, as well as by public and private research institutions and individual analysts. However, it only covers the manufacturing sector as a whole.

In measuring materials' inputs, the quality issue is focussed on whether the corresponding deflator used to obtain the real magnitude has been adjusted for quality change, so that it would reflect a "pure" price change. The same problem of quality adjustment exists for the output deflators as well. This paper does not consider the degree to which output and input deflators are adjusted for quality change.<sup>1</sup> However, the sensitivity of the results to partial adjustment for quality change may be important in areas where technological change has been rapid, as in the case of chemicals.

Our main data source is the Annual Industrial Survey (AIS) of the National Statistical Service of Greece (ESYE) at the three-digit ISIC (International Standard Industrial

<sup>&</sup>lt;sup>1</sup>. In Georganta (1992) the output deflators for the Greek manufacturing sector have been found to incorporate measurement errors, probably mostly attributable to partial adjustment for product-quality change of the corresponding price indices.

Classification) level. We have considered the "large scale" industry which includes manufacturing establishments with an annual average employment (aae) of 10 or more persons. The survey covers all manufacturing establishments of the country with an aae of 20 or more persons, and takes a sample of those manufacturing establishments with an aae of 10-19 persons.

The rest of our data sources are the wholesale and input price indices, both at the three-digit level, compiled by the ESYE. The wholesale prices include finished products of local industrial production for home consumption, and exported products of local industrial production. The input price indices correspond to the same three-digit industries as the wholesale price indices. They cover energy consumption, raw materials and intermediate products used in the production process. The classification of both wholesale and input price indices was adjusted to match the ISIC classification of the AIS.

The following table gives a picture of ten main economic variables of the whole manufacturing sector for the years 1980-1991.

Main Economic Variables of Manufacturing Activity, Large Scale, Greece 1980-1991

.

Table 1.1 shows that during 1980-1991 the number of establishments and employment is slightly decreasing for the Greek manufacturing sector considered as a whole. For those establishments employing 10-19 persons on average per annum (pa), employees' compensation in nominal terms has increased more than it has for the larger establishments, 22.2% average annual growth rate for the former and 18.9% pa on average for the manufacturing sector considered as a whole. Gross value of production, intermediate consumption, and sales have all increased by about 17%. Investment shows a lower record, 14.3% pa on average. In general, growth is higher for the smaller establishments. Intermediate input prices have increased by 14.6% and output prices have increased by 16.1% pa on average. It is noted that the inflation rate during 1980-1991, as measured by the consumer price index, was 19.7% pa on average.

In relation to capital stock, Skountzos and Mattheou (1991) data, as reported above, are only available for the manufacturing sector as a whole. We have obtained data at the three-digit ISIC level by the following procedure: For each year of the time period 1980-1991 we considered the sum of the fixed capital formation in buildings-structures, transport equipment and machinery-other equipment, reported in the AIS.<sup>1</sup> Let us denote this sum by  $s_{it}$ , where i refers to each three-digit industrial branch, and t is time, t = 1980, 1981,...,1991. Then, we consider  $\Sigma s_{it}$ , which is the sum of fixed capital formation from 1974 up to current year. In other words, for the year 1980,  $\Sigma s_{it}$  is the sum of fixed capital formation during the time period 1974-1980, for the year 1981  $\Sigma s_{it}$  is the sum of fixed capital formation during the time period 1974-1981, and so on. Next, we obtained the capital stock at the three-digit ISIC level as follows: For the year 1980 we distributed the capital stock figure, estimated by Skountzos and Mattheou (1991) for the year 1980, in proportion to each three-digit participation in the sum  $\Sigma s_{it}$  for the year 1980. For the rest of the years, 1981-1991, the capital stock at the three-digit ISIC level was obtained by increasing the capital stock of any year by the growth rate of the sum of fixed capital formation,  $\Sigma s_{it}$ , of the current year with respect to the previous year, taking the year 1980 as initial year.

The capital stock in constant prices was obtained by utilizing the implicit price deflators of Skountzos and Mattheou (1991) and assuming that they do not differentiate among the three-digit industries. This procedure has given very small differences between the capital stock for the whole manufacturing sector in this study and the Skountzos and Mattheou (1991) figures. The panel data on capital stock are presented in Table A.4 of the Appendix.

Tables 2.1 to 2.7 present summary statistics of our data at the three-digit ISIC level. As it is apparent in the above tables, our final number of industries is 96. There are

<sup>&</sup>lt;sup>1</sup>. For the years 1978 and 1979 there is no AIS.

all together 109 three-digit industries, but due to confidentiality issues (in cases that it is only one establishment reported) the following three-digit ISIC groups have been considered as one three-digit industry: 322 + 329,335 + 338 + 339,372 + 374 + 377,385 + 386 + 387 + 389,392 + 393,391 + 395 + 398. Also, industries 242 and 382 are not included in our final data set because of inconsistencies in the information reported. Table A.1 of the Appendix shows the two - and three - digit code titles of the respective industry groups and industries.

Tables 2.1 to 2.7 show that variation between the three-digit ISIC industries, as expressed by the coefficient of variation, cv, is very high for output, intermediate consumption, compensation of wage earners, and capital stock. During the whole period considered, 1980-1991, the cv is higher than one for these variables.

# <u>The Two- and Three-Digit ISIC Productivity Indices</u> <u>Capacity Utilization</u>

For the variables of this paper, formula (17) becomes,

$$TFP/TFP = Y/Y - v_{L}(L/L) - v_{M}(M/M) - v_{K}(K/K)$$
(19)

If subscripts 2 and 3 denote two-digit and three-digit ISIC respectively, we have:

$$Y_{3it}/Y_{3it} = (logY_{it}-logY_{i,t-1})$$
 (20)

$$Y_{2rt}/Y_{2rt} = w_{jit}(\log Y_{it} - \log Y_{j,t-1}), \ w_{jit} = [(gvp_{it}/\sum_{j=1}^{n} gvp_{jit}) + (gvp_{i,t-1} / \sum_{j=1}^{n} gvp_{ji,t-1})]/2$$
(21)

$$L_{3it}/L_{3it} = \{ [(s_{it}/\sum (s+w)_{it}) + (s_{i,t-1}/\sum (s+w)_{i,t-1})]/2 \} [log(se)_{it} - log(se)_{i,t-1}] + \\ + \{ [(w_{it}/\sum (s+w)_{it}) + (w_{i,t-1}/\sum (s+w)_{i,t-1})]/2 \} [log(we)_{it} - log(we)_{i,t-1}]$$
(22)

$$L_{2rt}/L_{2rt} = I_{jit}(L_{3it}/L_{3it}), \quad I_{jit} = \{[(se + we)_{it}/\sum (se + we)_{jit}] + [(se + we)_{j-1}/\sum (se + we)_{ji,t-1}]\}/2$$
(23)

$$M_{3it}/M_{3it} = [log(vtotcon)_{it}-log(vtotcon)_{i,t-1}]$$
(24)

$$M_{2rt}/M_{2rt} = m_{jit}[log(vtotcon)_{it}-log(vtotcon)_{i,t-1}],$$
  

$$m_{jit} = [(tot_{j=1}^{n}m_{jit}/\sum totcon_{jit}) + (totcon_{i,t-1}^{n}/\sum totcon_{ji,t-1})]/2$$
(25)

$$K_{3it}/K_{3it} = [log(vcapst)_{it}-log(vcapst)_{i,t-1}]$$
(26)

$$K_{2rt}/K_{2rt} = k_{jit}(K_{3it}/K_{3it}),$$
  

$$k_{jit} = [(capst_{ji}/\sum_{j=1}^{n} capst_{jit}) + (capst_{ji}t_{1})/\sum_{j=1}^{n} capst_{ji,t-1})]/2$$
(27)

where,

i : 201,...,399, three-digit industries

j: 1,...,n, n = number of three-digit industries included within each two-digit industry group

- $r: 20, 21, \dots, 39$ , two-digit industry groups
- t:1980,...,1991
- s : compensation of salaried employees

t: 1980,...,1991

s : compensation of salaried employees w : compensation of wage earners se: Number of salaried employees we: Number of wage earners totcon : total intermediate consumption vtotcon: volume of total intermediate consumption capst : capital stock

vcapst : volume of capital stock

Any partial productivity index is estimated on the basis of equation (19) as a difference, Y/Y - X/X, where X is any of the three inputs, labor, intermediate consumption, and capital. It is easily observed that the above Divisia-Tornquist indices of output, input, TFP and partial productivity are chain-linked. For each year the current values are used as a base in estimating the rate of growth to the following year. The advantages of chained indices are thoroughly discussed in Diewert (1986).

The three-digit ISIC level capital stock series, which have been obtained as described above, have to be transformed into flows of capital services, since the production function is conventionally interpreted as a relationship between the flow of output and the flow of input services. One approach could be to assume that capital flows are proportional to stocks, so that the one is a perfect surrogate for the other. In such a case, capital utilization (ratio of flow to stock) is assumed to remain constant over time and, in particular, over the business cycle, which is an unrealistic assumption. Another approach is to multiply the estimated capital stock by an estimate of capital utilisation. This has been applied by various researchers, as Jorgenson and Griliches (1967, 1972), by considering the ratio of used energy to installed energy as a proxy for capacity utilisation. This proxy variable is not available for the Greek manufacturing sector.

Another approach to the capacity utilization problem, which has been followed in this paper, is to introduce into the analysis the distinction between the long-run and the short-run by assuming that capital is a quasi-fixed factor (fixed in the short-run and variable in the long-run).<sup>1</sup> Within this framework, capacity utilisation is defined as the ratio of actual output, Y,

<sup>&</sup>lt;sup>1</sup>. See Berndt and Fuss (1986) and Hulten (1986, 1990).

to capacity output,  $Y_0$ . At capacity level of output  $Y_0$ , the short-run and the long-run unit cost curves are at their minimum. Thus, it is assumed that  $Y \neq Y_0$ , leading to a gross quasirent or ex-post rental price, Z, realized from the capital stock when the other inputs are adjusted to meet fluctuations in demand. Z is thus the residual income accruing to the quasifixed stock (revenue minus payments to all variable inputs):

$$Z = (qY - pX^{\neq K})/KS$$
(28)

where q, p are prices for output and inputs (except for capital) respectively, K is capital input, and KS is capital stock. Berndt and Fuss (1986) showed that Z equals the value of the realized marginal product of capital in each period. Jorgenson and Griliches (1967) and Christensen and Jorgenson (1969) constructed such a measure, but they did not develop it theoretically as Berndt and Fuss (1986) did. For this paper, Z is non-parametrically estimated and the capital stock is transformed into a capital input argument by adjusting the corresponding factor shares. According to this approach, the weights v in equation (19) are defined as follows: By assuming constant returns to scale, we have,

$$GVP = Z^{\kappa}KS + P^{L}L + P^{M}M = Z^{\kappa} = (GVP - P^{L}L - P^{M}M)/KS$$
(29)

Then, 
$$v_{L} = P^{L}L/GVP$$
,  $v_{M} = P^{M}M/GVP$ ,  $v_{\kappa} = Z^{\kappa}KS/GVP$  (30)

Thus,  $Z^{K}$  is Berndt and Fuss's (1986) quasi-rent, or shadow rental price of capital.

Consequently, our capital input is adjusted for over- or under- capital utilization. Within this framework, it is easily proved that capital utilization is given by the formula:  $cu = Z^{K}/P^{K}$ , where  $P^{K}$  is the market rental price of capital. If cu > 1, unit cost is rising because of decreasing returns to the increasingly utilized fixed capital stock. If cu < 1, unit cost is falling, and if cu = 1, then the firm's output equals its capacity output and average cost is at a minimum.

By utilizing the methodology developed thus far, we have estimated TFP and partial productivity indices for the manufacturing sector of Greece. The estimates are presented in the following section.

### 4. The Estimates

The estimated TFP indices at the three-digit, as well as the two-digit ISIC level are presented in tables A.2 and A.3 of the Appendix, respectively. The next Tables 3.1 to 3.7 present summary statistics of the estimated TFP, output, input, partial productivity indices, capital utilization ratios, and the shares of labor, intermediate consumption, and capital, all at the three-digit ISIC level.<sup>1</sup>

# TABLE 3.1 Summary Statistics of TFP Chain-Linked Indices, at the Three-Digit ISIC Level

Variable	Obs	Mean	Std. Dev.	Min	Max
tfp81	96	96.31	10.78	38.60	135.83

On the basis of Tables A.2 and A.3 we can distinguish the following categories of TFP behavior:

(1) A growth trend during the entire period. For example, the following industries belong to this category: 204, 213, 221 and 222, 259, 332, 337, 361, 368, 383. We call these industries "Dynamic".

(2) A growth trend until 1985 or 1986, followed by a decline thereafter. For example, the following industries belong to this category: 207, 236, 237, 244, 367, 381. We call these industries "EC-Undesirable". We note that Greece officially joint the EC (European Community) in 1981, but the time period 1981-1985 was a transition period.

(3) A growth trend from 1986 or 1987. Examples of this group behavior include the following industries: 209, 393, 394, 398. We call these industries "EC-Favored".

(4) Finally, a declining time path includes industries like the 205, 272, 301, 378. We call these industries "Dying".

Another observation based on Table A.2 is that since 1986 there is a declining number of industries which shows an increase in TFP with respect to the previous year. The actual number of these industries during 1980-1991 is shown in the following table:

TABLE 4.1
Number of Three-Digit Industries Showing an Increase in
TFP Indices, 1980-1991

1981	1982	1983	1984	1985	1986	1987	1988	1989	1990	1991
30	39	42	58	62	51	44	50	59	49	21
	11	5	4	3	2	0				

The second line of Table 4.1 shows that only 11 out of the 30 industries showing an increase in 1981 also show an increase in 1982; this number becomes 5 for 1983, and in 1987 there are no common industries which show an increase during 1980-1987 included.

Tables 3.1 to 3.8 show that for some industries, although output has grown satisfactorily, the intermediate inputs used have grown even "more satisfactorily", being responsible for a stagnant or falling TFP growth rate. Regarding partial productivity indices, shown in Tables 3.4, 3.5, and 3.6, we observe that labor productivity has increased, most probably because of the reduction or non-increase in the number of persons employed. Intermediate-inputs productivity is rather falling, while capital productivity is slightly

Intermediate-inputs productivity is rather falling, while capital productivity is slightly increasing, with the exception of 1991 that records a -15.7% decrease in relation to 1990.

Capital utilization ratios are below unity for all two-digit manufacturing industries, meaning decreasing unit costs. Factor shares in Table 3.8 show that intermediate consumption absorbs most of the sector's income, more than 60% on average. Capital follows with a share slightly above 20%. Labor scores last with a share of slightly below 20%. The minus signs in Tables 3.7 (capital utilization) and 3.8 (share of capital) are explained by the fact that some three-digit ISIC industries, in particular years, generated a gross value of output well below their expenditures for intermediate consumption and employees' compensation summed together. The result was a negative outcome in equation (29).

#### 5. Conclusions

This paper has used the traditional growth accounting statistical framework in order to compute partial and total factor productivity indices for the manufacturing sector of Greece during the time period 1980-1991. It has covered a gap existing in the coverage of the official economic statistics for manufactures in Greece. This data base is particularly useful for a scientifically based policy analysis regarding the Greek manufacturing sector. One of the immediate conclusions that come out of this data is that a number of industries, the "dynamic", may be considered under a set of policy measures which differentiates from that set of policy measures directed towards the "dying" or "EC-undesirable" industries. Also, the development of "EC-favored" industries could be analysed so that we could draw some lessons or conclusions for other industries.

# APPENDIX

Titles of ISIC Codes, TFP at the Three-Digit and Two-Digit ISIC

Titles of ISIC Two - and Three - Digit Codes

## 20 Food and Kindred Products

- 201 Meat Products
- 202 Dairy Products
- 203 Canned, Frozen, and Preserved Fruits, Vegetables, and Food Specialties
- 204 Fats and Oils
- 205 Grain Mill Products
- 206 Bakery Products
- 207 Sugar
- 208 Chocolate and Confectionery Products
- 209 Miscellaneous Food Preparations and Kindred Products

#### 21 Beverages

- 211 Alcoholic Drinks and Alcohol
- 212 Wines
- 213 Beer
- 214 Non-alcoholic Drinks, Mineral Water
- 22 Tobacco Manufactures
- 221 Tobacco
- 222 Cigarettes and Cigars

## 23 Textile Mill Products

- 231 Manmade and Natural Wool Fiber and Fabrics
- 232 Manmade and Natural Cotton Fiber and Fabrics
- 233 Manmade and Natural Silk Fiber and Fabrics, and Nylon Fiber
- 234 Manmade Fiber and Fabrics, except Nylon
- 235 Jute, Linen and Canvas and Related Products
- 236 Knitting Mills
- 237 Coloring, Printing and Finishing Plants
- 238 Threads and Yarns
- 239 Miscellaneous Textiles

#### 24 Apparel and Other Textile Products

- 241 Shoe Making
- 242 Shoe Repair
- 243 Apparel
- 244 Clothing and Other Textile Goods

#### TABLE A.1 (Continued)

### 25 Lumber, Wood and Cork Products

- 251 Sawmills and Planing Mills
- 252 Construction Wood Works
- 253 Wood Containers and Small Wood Goods
- 259 Cork and Cork Products

#### 26 Furniture and Fixtures

- 261 Wood Household Furniture
- 262 Metal Household Furniture

### 27 Paper and Allied Products

- 271 Pulp and Paper Mills
- 272 Paper Products

#### 28 Printing and Publishing

- 281 Printing and Editing of Newspapers, Journals, Books and Pamphlets
- 282 Miscellaneous Printing Works

## 29 Leather, Leather Products and Furs

- 291 Leather Plants
- 292 Fur and Fur Products, Except Apparel
- 293 Manmade and Natural Leather Products, Except Apparel and Shoes

## 30 Rubber and Miscellaneous Plastics Products

- 301 Rubber Plants
- 302 Miscellaneous Plastics Products

## 31 Chemicals and Allied Products

- 311 Acids, Salts and Fertilizers
- 312 Plastics Materials and Resins, Manmade Fibers
- 313 Other Primary Chemical Plants
- 314 Paints, Printing Inks and Allied Products
- 315 Pharmaceuticals
- 316 Cosmetics, Perfumes and Toilet Preparations
- 317 Soaps and Detergents
- 319 Miscellaneous Chemicals Products

#### 32 Petroleum and Coal Products

- 321 Petroleum Refining
- 322 Coal Products and Lignite
- 329 Petroleum Byproducts
- 33 Non-metallic Minerals and Allied Products

#### TABLE A.1 (Continued)

- 331 Minerals and Earths for Structures
- 332 Glass and Glass Products
- 333 Clay, Porcelain and Related Products
- 334 Cements
- 335 Lime, Gypsum and Related Products
- 336 Cement Products
- 337 Marble and Marble Products
- 338 Asbestos Products
- 339 Miscellaneous Non-Metallic Minerals Products

#### 34 Primary Metal Industries

- 341 Iron
- 342 Other Metals

# 35 Fabricated Metal Products, except for Machinery and Transport Equip.

- 351 Iron Tubes
- 352 Chains, Wire Springs, Nails and Related Products
- 353 Metal Structures
- 354 Metal Tools
- 355 Household Metal Appliances
- 356 Cast Iron Products
- 357 Copper and Lead Products
- 358 Aluminum Products
- 359 Miscellaneous Metal Products, except Machinery and Transport Equip.

#### 36 Machinery Except Electrical

- 361 Internal Combustion Engines
- 362 Air Conditioning Machines
- 363 Agricultural Machinery
- 364 Machinery for Roads, Quarries and Structures
- 365 Machinery for the Food, Beverages and Tobacco Industries
- 366 Machinery for the Textile, Wood and Metal Industries
- 367 Pumps, Blowers and Industrial Spraying Machinery
- 368 Office Equipment and Balances
- 369 Machinery and Repair non specifically Named

## 37 Electric and Electronic Equipment

- 371 Electrical Machinery
- 372 Transformers and Dry Electrical Elements

#### TABLE A.1 (Continued)

- 373 Electrical Coil Windings and Electrical Wiring
- 374 Lamps and Lighting Fixtures
- 375 Other Electrical Materials
- 376 Telecommunications, Materials and Hearing Devices
- 377 Electrical Scientific Instruments
- 378 Other Electrical Apparatuses
- 379 Repair of Electrical Equipment

#### 38 Transportation Equipment

- 381 Boats and Repair
- 382 Rail Materials
- 383 Cars
- 384 Car Repair
- 385 Motorcycles and Bikes
- 386 Repair of Motorcycles and Bikes
- 387 Repair of Airplanes
- 389 Other Transportation Equipment

# 39 Miscellaneous Manufacturing Establishments

- 391 Medical Instruments, Measuring and Control Instruments
- 392 Photographic and Optical Products
- 393 Repair of Photographic and Optical Products
- 394 Watches and Cosmetics
- 395 Repair of Watches
- 396 Musical Instruments
- 397 Toys and Athletics Products
- 398 Manmade Teeth
- 399 Miscellaneous Plants
